Marks

/ 10

- 1 (a) State the type of reaction and draw the structural formula of the organic product formed when the following compounds reacts with each of the following reagent. [3]

(i) Hot acidified potassium dichromate(VI)

[1] for structure

Type of reaction: Oxidation

(ii) Ethanoyl chloride,  $\text{CH}_3\text{COCl}$

[1] for structure

Type of reaction: condensation / nucleophilic acyl substitution

The acyl chloride will react with both the alcohol groups

[1] for type of reaction for both (i) and (ii)

- (b) Draw the structure of the organic product formed when the following compound reacts with each of the following reagent. [2]

<p>(i) Aqueous bromine</p> <p>[1]</p>	<p>(ii) Hot, alkaline potassium manganate(VII)</p> <p>[1]</p> <p>Accept Na<sup>+</sup>/K<sup>+</sup> as counter ion or no counter ion.</p> <p>Phenol undergoes acid base reaction with the alkaline medium, while the carbon containing side chain of benzene undergoes oxidation.</p> <p><i>Note that the side pdt ethandioic acid will be further [O] to CO<sub>2</sub> and H<sub>2</sub>O; and turned to inorganic pds CO<sub>3</sub><sup>2-</sup> and H<sub>2</sub>O.</i></p>
---------------------------------------	---

Explanation for 1b(i)

more stable **benzylic carbocation**, as the p orbital of the  $sp^2$  carbocation can overlap with the delocalised  $\pi$  electron cloud of the benzene ring.

less stable, will not be formed

- 2 State how propan-1-ol and propan-2-ol could be distinguished by a simple chemical test. Give the observation and write equations for any reaction(s).

Test: Add NaOH(aq), I<sub>2</sub>(aq), warm

Observation: Yellow ppt of CHI<sub>3</sub> formed for propan-2-ol, no yellow ppt for propan-1-ol (must state both positive and negative observations for both alcohols)

[1] for test and observations

Equation(s):

[1] for eqn

propan-1-ol	$\begin{array}{ccccc} & \text{H} & & \text{H} & & \text{H} \\ &   & &   & &   \\ \text{H} & -\text{C} & - & \text{C} & - & \text{C} & -\text{O}-\text{H} \\ &   & &   & &   \\ & \text{H} & & \text{H} & & \text{H} \end{array}$	propan-2-ol	$\begin{array}{ccccc} & \text{H} & & \text{H} & & \text{H} \\ &   & &   & &   \\ \text{H} & -\text{C} & - & \text{C} & - & \text{C} & -\text{H} \\ &   & &   & &   \\ & \text{H} & & \text{O} & & \text{H} \\ & & &   & & \\ & & & \text{H} & & \end{array}$
-------------	--	-------------	--

- 3 Explain why ethanol is a weaker acid than phenol in terms of the Bronsted-Lowry theory. [3]

(Ethanol and phenol are Bronsted-Lowry acids as they are **proton donors**. Strength of the acid depends on the stability of the conjugate base)

The ethoxide ion (C<sub>2</sub>H<sub>5</sub>O<sup>-</sup>) is **less stable** than the phenoxide ion as the **negative** charge on the O atom is intensified by an **electron donating alkyl group**, hence **destabilising it**. Ethanol is therefore less acidic, and **donates protons less readily** and **POE of the ethanol dissociation lies more to the left**.

The phenoxide ion is more stable as the **p orbital of O overlaps with the π orbitals of benzene ring** resulting in the delocalisation of lone pair of electrons on the O atom into the benzene ring. **Negative** charge on O atom is dispersed over the benzene ring and one oxygen atom, hence **stabilising it**. Therefore phenol is more acidic and it **donates a proton more readily** and **POE of the phenol dissociation lies more to the right**.

total [3] for all 3 marking points:

- stating that ethoxide ion is less stable than the phenoxide ion
- explanation of stability of each conjugate base
- stating the POE of dissociation of each acid
