# Nov 2015 H2 Bio Paper 2

N15P2Q1	
(a)	Identify the structures A and B, as shown in Fig.1.1. [6] For each structure, state <b>two</b> features that can be seen in Fig.1.1.
	structure <b>A</b> : mitochondrion (R: mitochondria) feature 1: double membrane feature 2: highly folded inner membrane/cristae structure <b>B</b> : rough endoplasmic reticulum feature 1: flattened sacs called cisternae studded with ribosomes feature 2: continuous with outer membrane of nuclear envelope
(b)	Describe two functions of the Golgi body.[2]
	<ol> <li>To <u>glycosylate proteins and lipids</u> to form glycoproteins and glycolipids respectively;</li> <li>To <u>modify existing glycoproteins and glycolipids</u> by modifying/cleaving the existing sugar chains;</li> </ol>
	3. To <u>sort and package proteins</u> into different vesicles and <u>target the proteins to</u> <u>different parts of the cell or for secretion;</u>
	<ul> <li>4. To <u>form lysosomes;</u></li> <li>5. To <u>synthesise polysaccharides</u> such as <u>pectin</u> which is <u>transported in vesicles to the cell membrane;</u></li> </ul>
(c)	Suggest two advantages to eukaryotic cells of having membrane bound organelles.[2]
	Membranes allows for compartmentalisation which allow 1. <u>unique environments</u> to be formed for highly <u>specialised activities</u> (e.g. <u>acidic environment in lysosomes for hydrolytic enzymes to work</u> );
	<ol> <li>spatial separation of biochemical processes &amp; thus their sequential operation within a cell (e.g. protein modification in RER and further protein modification, sorting and packaging in the GA);</li> </ol>
	<ol> <li>accumulation of ions to high concentrations (e.g.accumulation of a high concentration of H+ in the intermembrane space of the mitochondria enable a proton gradient to be established for chemiosmosis);</li> </ol>
	4. Membranes act as a <u>surface for chemical reactions to occur in a sequential manner</u> membranes may have functionally-related proteins grouped together so that sequential biochemical processes can occur (e.g. the <u>thylakoid membranes of the chloroplast have electron carriers &amp; ATP synthetase for chemiosmosis to occur</u> );
	5. Membranes increase surface area for chemical reactions (e.g. inner mitochondrial membrane is highly folded to hold more electron transport chains and ATP synthetase);
(d)	<ul> <li>Explain the role of glycogen in animal cells.[2]</li> <li>1. Glycogen is an <u>large energy store</u> found in the liver and muscles;</li> <li>2. which can be <u>hydrolysed</u> to many <u>glucose molecules</u> that can be used as a <u>respiratory substrate</u> which oxidized during respiration to <u>produce ATP</u>.</li> </ul>

[Total :12]

N15P2Q2					
(a)	Describe how replication of the lagging strand template occurs. [2]				
		ging strand is <u>synthesised discontinuously</u> in fragments known as			
			gments. Each fragment is initiated by an <u>RNA primer</u> before the		
			DNA nucleotides;		
			ses the <u>RNA primer</u> and <u>replaces it with</u>		
			seals the nicks by forming phosphodiester		
			of the each of the DNA fragments on the		
	new strand	·			
			ymerase* works only in the 5' to 3' direction.		
			nds in opposite directions with respect to the		
	replication fork. i.e. The leading strand is being synthesized towards the replication fork while				
	the lagging strand is being synthesized away from the replication fork due to the anti parallel				
	nature of the 2 template strands.				
(b)	State 2 ways in which DNA replication,				
(i)		differs from transcription,			
~ / /					
		DNA replication	Transcription		
	1. Product	Double-stranded DNA	Single-stranded mRNA		
	2. Enzymes	DNA polymerase links	RNA polymerase links		

nucleoides

replication

2. Both processes occur in the nucleus;

to initiate DNA

**RNA primer is required** 

1. Both use DNA as a template to synthesise the complementary strand;

3. Nucleotides in the nucleic acid that is synthesized are linked by phosphodiester

3. Primer

bonds;

(ii)

requirement

is similar to transcription.

nucleotides

RNA primer is NOT required to

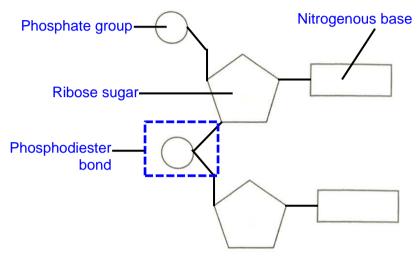

initiate DNA replication

(c) The symbols below represent the main components of RNA.

In the space below, draw a short section of mRNA that is made up of two nucleotides, using these symbols to represent the main components. Add lines to show the positions of any bonds between the components.

Label and name the components and the covalent bond that links the nucleotides.[3]

- 1. Phosphate group linked to carbon number 5 of ribose sugar and nitrogenous base linked to carbon number 1 of ribose sugar;
- 2. Correct labels for phosphate group, ribose sugar and nitrogenous base;
- 3. Phosphodiester bond correctly identified and labelled

#### N15P2Q3

- (a) (i) Name structures S and T, as shown in Fig. 3.1. [2]
  - 1. S: *promoter*\*;
  - 2. T: <u>operator\*</u>;
  - (ii) Identify a structural gene in Fig. 3.1 and explain what is meant by the term, structural gene. [1]
    - <u>lacZ / lacy / lacA gene</u> + Structural gene is any gene that codes for a <u>protein product</u> that has an <u>enzymatic function</u> in a <u>metabolic pathway;</u>
  - (iii) Identify a regulatory gene in Fig. 3.1 and explain what is meant by the term, regulatory gene. [1]
    - <u>lacl gene</u> + Regulatory gene codes for a <u>protein</u> (e.g. repressor) involved <u>regulating</u> <u>expression of structural genes;</u>

- (b) Using Fig. 3.1, describe how the presence of lactose induces a bacterium to use lactose as a respiratory substrate. [3]
  - Lactose is converted to its isomer <u>allolactose</u> which acts as an <u>inducer</u> to <u>bind</u> to the active <u>repressor protein</u> at its <u>allosteric site</u>;
  - 2. This makes the repressor inactive as it <u>alters the conformation of the DNA-</u> binding site of the repressor and which then can <u>no longer bind to the operator;</u>
  - <u>RNA polymerase</u> is now free to <u>bind to the promoter</u> and can move downstream to <u>transcribe</u>\* the structural genes to form <u>β-galactosidase</u>, permease and <u>transacetylase</u> for metabolism of lactose;

[Total: 7]

## <mark>N15P2Q4</mark>

Fig. 4.1 shows the development of a metastatic cancer in the colon over a period of ten or more years. Metastatic is a term used to describe cancer that is spreading from one organ to another. *APC*, *ras* and *p53* are tumour suppressor genes. *(error: ras is proto-oncogene!!)*\*\*\*

- (a) State two environmental causes of cancer. [2]
  - 1. <u>ultraviolet light</u> / radioactivity / ionizing radiations (mention of radiation alone not sufficient as visible light also emits radiation);
  - 2. Carcinogens such as <u>tar</u> in cigarette smoke, <u>asbestos, benzene, formaldehyde,</u> <u>ethidium bromide</u> etc. (give named example);

### (b) With reference to Fig. 4.1, explain why cancer development is a multi-step process. [3]

1. The development of cancer requires the <u>accumulation of mutations</u> in the genes in a <u>single cell</u>; [1]

Idea of accumulation of different mutations using Fig. 4.1 (1mark for any two points 2,3,4)

- 2. <u>Loss-of- function mutation</u> in <u>2 copies/alleles</u> of APC <u>tumour suppressor</u> gene results in dysregulation of cell cycle to have excessive cell division;
- Gain-in-function mutation in just one copy/allele of ras proto-oncogene to ras oncogene results in hyperactive/excessive ras protein to form tumour/mass of cells;
- Loss-of- function mutation in <u>2 copies/alleles</u> of p53 <u>tumour suppressor</u> gene results in further dysregulation of cell cycle to have excessive tumour/mass of cells;
- 5. Chromosomal aberrations and other events (such as activation of telomerase, loss of contact inhibition, angiogenesis) occur to eventually lead to <u>metastasis;</u> [1]

# (c) Describe how dysregulation of the checkpoints of cell division may lead to cancer. [2]

 Ref to dysregulation of any one of the three checkpoints in cell cycle: <u>M checkpoint</u> dysregulated thus if any <u>chromosomes are not attached to spindle</u> <u>fibres</u>, the cell continues into metaphase and anaphase to produce genetically altered cell/mutant cell; OR

 $G_1 / G_2$  checkpoint dysregulated thus damaged DNA not repaired and cell continues into the M phase, accumulating the mutations;

2. Uncontrolled cell division / excessive cell division that leads to tumour/a mass of cells;

- Loss-of-function mutation of tumor suppressor genes causes <u>no functional</u> <u>gene products/proteins</u> to form; As a result,
- 2. unable to stop cell cycle to allow repair any damaged DNA;
- 3. <u>unable to activate DNA repair mechanism</u> to repair damaged DNA thus accumulation of mutations occurs;
- 4. <u>unable to initiate/promote apoptosis</u> thus cell with potential to cause cancer is not removed;

[Total: 10]

# N15P2Q5

In guinea pigs, the black coat allele **B** is dominant to the white coat allele **b**, and the straight hair allele **H** is dominant to the wavy hair allele **h**.

A guinea pig with a black coat and straight hair was crossed with a guinea pig with a white coat and wavy hair. The resultant offspring all had black coats with straight hair.

All these offspring were then crossed with guinea pigs having white coat and wavy hair in a series of test crosses.

The following progeny were produced from the test crosses :

Black coat, straight hair	30
Black coat, wavy hair	10
White coat, straight hair	12
White coat, wavy hair	31
Total	83

(a) Using the symbols for the alleles stated above, draw a genetic diagram t show the expected phenotypic ratios for the offspring of the test crosses if the inheritance is Mendelian.

Offspring genotype	BbHh	Bbhh	bbHh	bbhh
Offspring	Black coat	Black coat	white coat	white coat
phenotype	straight hair	wavy hair	straight hair	wavy hair
Phenotypic ratio	1	1	1	1

1m for correct parental phenotype and genotype ;

1m for correct gametes which are circled ;

1m for correct offspring genotype and phenotype ;

1m for correct phenotypic ratio;

- (b) Explain why there is a greater number than expected of the parental phenotypes. [3]
  - 1. The genes coding for coat colour and hair texture are linked on the same chromosome;
  - 2. <u>Alleles</u> for <u>black coat and straight hair</u> are linked on the <u>same chromosome</u>;
  - 3. <u>Alleles</u> for <u>white coat and wavy hair</u> are linked on the <u>same chromosome</u>;
  - 4. <u>Greater chance</u> for these alleles to be <u>inherited together</u>, thus resulting in <u>greater</u> <u>number</u>;
  - 5. <u>Number of recombinants are smaller because crossing over/recombination</u> is a <u>chance event</u> and the <u>frequency of recombination</u> is dependent on the <u>distance</u> <u>between the two genes;</u>
- (c) Describe how it is possible for progeny with black coats and wavy hair to be produced from these test crosses. [3]
  - 1. During prophase I of meiosis I, crossing over\* occurs between non-sister chromatids of homologous chromosome\*;
  - 2. At the *chiasma*\*, portion of chromatid containing allele **B** <u>break and rejoin</u> to portion of chromatid containing allele **h**;
  - 3. Resulting in <u>new linkage group</u> being formed where the <u>allele **B**</u> that codes for black coat and the <u>allele **h**</u> that codes for wavy hair are <u>linked on the same chromosome</u>;
  - 4. <u>Gamete</u> that contained chromosome <u>that contain allele</u> **B** linked to allele **h** fuses with <u>gamete</u> that contain chromosome that <u>contain allele</u> **b** linked to allele **h**;

# <mark>N15P2 Q6</mark>

 (a) Receptors for some hormones are found within their targets. Explain why insulin receptors are found on the cell surface membranes of target cells and never within the cells. [2]
 1. Insulin is too large, cannot pass through any transient pores form within cell surface membrane;
 2. cannot pass through hydrophobic core of cell surface membrane because it is bas

 <u>cannot pass through hydrophobic core</u> of cell surface membrane because it is has polar regions and will be repelled;

<u>Comments:</u> Do note that insulin receptors actually exist as linked dimers. Since this question shows the 2 subunits dimerising, you need answer the question according to the figure.

(b)

- Use Fig. 6.1 to explain how the presence of insulin is able to trigger a response inside the target cell.
  - 1. Insulin has a <u>specific 3D conformation</u>\* that is <u>complementary</u>\* to the <u>extracellular ligand-binding site</u> of the <u>insulin receptor</u>;
  - This ensures <u>specificity</u> in binding between insulin and the insulin receptors resulting in the <u>dimerization</u>\* of <u>two receptor subunits;</u>
  - 3. <u>Conformational change</u> in the <u>intracellular</u> domain of receptor results in <u>activation</u> of intrinsic tyrosine <u>kinase</u>;
  - 4. Intrinsic tyrosine kinase activity of each subunit in the intracellular domain <u>cross-phosphorylates /autophosphorylates</u> the **tyrosine**\* residues on the other subunit;
  - 5. Other <u>relay proteins</u> inside the target cell will be able to <u>bind to the phosphorylated</u> <u>tyrosine residues</u> and <u>become activated</u> themselves;

This will enable the signal to be transduced within the cell until an appropriate cellular response is reached.

Raffles Institution		stitution Nov 2015 (H2 Biology) Paper 2 (for 9744 syllabus)	2017
(c)	Usi	ng Fig. 6.2., describe the main effects of insulin on different target cells.	[6]
	1.	Binding of insulin to the insulin receptor will lead to cellular responses such as t	to trigger
		the translocation of vesicles with glucose transporter-4 (GLUT4)* to the	
		membrane of the target cells;	
	2.	This will increase the number of glucose transporters (GLUT4) on the plasma mer	<u>mbrane;</u>
	3.	increasing the permeability of the plasma membrane to glucose. There will be an	
		in the uptake of glucose from the blood by these cells, causing blood	glucose
		concentration to drop;	
	4.	The glucose taken up by the cells will be used to synthesize glycogen* via a	series of
		condensation reactions (i.e. glycogenesis);	
	5.	Glycogen synthesis is catalyzed by glycogen synthase,	
	6.	which is an enzyme <u>activated</u> as a result as the insulin signalling;	
	7.	The glucose taken up by the cells will increase the rate of glycolysis and can	
		broken down by aerobic respiration to form intermediates (e.g. acetyl coA) whic	h is then
		used for <u>fatty acid synthesis</u> *;	
	8.	This process is catalysed by various enzymes which are activated as a result of	of insulin
		signalling.

- 1. They are <u>objective</u>. Molecular <u>character states are unambiguous</u> as A, C, G and T are easily recognisable and cannot be confused;
- 2. Data is <u>quantitative</u> and easily converted to <u>numerical</u> form for <u>statistical analysis</u>. The <u>degree of relatedness can be inferred</u> and quantified by <u>calculating</u> the <u>nucleotide differences between species</u>;
- 3. Furthermore the <u>mtDNA does not undergo recombination</u> thus any changes to DNA is due solely to the accumulation of mutations over time making it the ideal candidate for a <u>molecular clock</u>. We can thus estimate the time of speciation;

- (d) Suggest, with reference to Fig.7.1 and Fig. 7.2, why breeding between *C. lunulatus* and *C. trifasciatus* is possible. [3]
  - 1. Since C. lunulatus and C. trifasciatus share a common ancestor (as seen in Fig 7.1);
  - 2. and there are <u>areas</u> where they are <u>found overlap</u> (as seen in Fig.7.2);
  - 3. they are able to interbreed and form hybrids;

[Total :13]

N15P2Q	8	
(a)	Descrit	pe how DNA is arranged in the two structures. [4]
		1. <u>Eukaryotic DNA coils around</u> proteins called <u>histones</u> to form nucleosomes;
	2	2. followed by coiling around itself to form solenoid / 30nm chromatin fiber and
		solenoid associates with scaffold proteins forming looped domains / 3000 nm
		fiber;
		3. <u>Supercoiling</u> of the loops to condense into the metaphase chromosome;
		4. Eukaryotic DNA is linear and prokaryotic DNA is circular;
		5. Prokaryotic DNA is associated with relatively fewer proteins (e.g. histone-like
		proteins) to form <u>loops</u> and there is <u>supercoiling</u> to cause further compaction;
(h)	Stata t	we wave in which the organization of genes found in these two structures differ and
(b)		wo ways in which the organisation of genes found in these two structures differ and store advantage of this to the bacterium. [3]
		1. In bacteria functionally related genes are organised into an <u>operon</u> which
		consists of an promoter, operator and structural genes while in eukaryotes
		usually not organised into operon;
		2. <u>One promoter controls expression of more than one gene</u> in bacteria while in
	-	eukaryote one promoter controls expression of one gene;
		Advantage of having operons in bacteria: [1 mark max]
	:	3. Operons having related genes expressed under the control of one promoter
		allows for fast response to environmental changes. This is important as bacteria
		are unicellular and exposed to fluctuating environment.
	4	4. Functionally related genes in an operon are expressed together as a set when
		necessary for economical use of energy and resources;

- Outline the behavior of chromosomes during meiosis
  1. At <u>prophase I\*</u>, <u>chromatin\*</u> coils, shortens and thickens into a <u>condensed</u> <u>chromosome</u>;
- <u>homologous chromosomes</u>\* pair up by a process called <u>synapsis</u>\* to form a <u>bivalents</u>\*;
- 3. Chiasmata\* formation and crossing over\* occurs;
- such that <u>exchange of equivalent portion of genetic material or alleles</u> occur between <u>non-sister chromatids</u>\* of <u>homologous chromosomes</u>\*;
- 5. <u>At metaphase I\*</u>, <u>homologous chromosomes\*</u> arranged as <u>pairs</u> at <u>metaphase plate/equator\*;</u>
- 6. <u>At **anaphase I**\*</u>, each <u>homologue</u> is <u>pulled</u> by a shortening <u>kinetochore</u> <u>microtubule</u> (that attaches to the centromere) towards <u>opposite poles</u> ;
- 7. <u>At **anaphase II**</u>\*, <u>centromeres\* divide</u> and <u>sister chromatids</u> separate to form daughter chromosomes and;
- 8. are <u>pulled</u> by a <u>shortening kinetochore microtube</u> (that attaches to the centromere) toward <u>opposite poles;</u>
- 9. <u>At **telophase** II</u>\*, <u>chromosomes</u> reach the <u>poles</u> of the spindle where they <u>decondense</u> and become <u>diffuse/indistinct;</u>

#### (c) Explain the role of nuclear envelope and centrioles during meiosis. Nuclear Envelope

[6]

- 1. Nuclear envelope is made of <u>double membrane</u> made up of <u>phospholipid</u> <u>bilayers;</u>
- During prophase I, nuclear envelope <u>disintegrate</u>\* so that <u>spindle fibres</u> can attach to the <u>centromere</u>\* and the <u>chromosomes can be pulled to</u> <u>opposite poles</u>;
- 3. During <u>telophase II</u>, <u>nuclear envelope reforms</u> around the chromosomes to form the <u>nucleus</u>;

Centrioles

- 4. A *pair*\* of cylindrical, rod-like structures;
- 5. which are *perpendicular/right angle/ 90°\** to each other;
- 6. Each consists of <u>9 triplets</u>\* of <u>microtubules</u>\* arranged in a <u>ring;</u>
- 7. After the centrioles replicate during interphase, the two pairs of centrioles move to opposite poles\* during prophase\*;
- 8. The centrioles become part of the *microtubule-organising centre*\* in which the <u>assembly of spindle fibres</u> and asters occur;
- 9. Spindle fibres are needed for the <u>separation of chromosomes and</u> <u>chromatids</u> during meiosis I and II;

(a) Describe the role of NAD and FAD in cellular respiration.

[6]

- Organic molecules are oxidized during *glycolysis, link reaction and Krebs* <u>cycle</u>\* and the <u>electrons</u> (and protons) from the oxidation process are transferred to the coenzymes *NAD*<sup>+\*</sup> and *FAD*<sup>+\*</sup> to form *NADH*<sup>\*</sup> (reduced NAD<sup>+</sup>) and *FADH*<sup>\*</sup> (reduced FAD<sup>+</sup>) respectively;
- NAD and FAD serves as <u>mobile electron (and proton) carriers</u> to carry the high energy electrons and protons from these organic molecules to the <u>electron transport chain</u>\* on the cristae of mitochondria;
- High energy electrons in NADH and FADH are used to <u>reduce electron</u> <u>carriers</u> of the <u>electron transport chain</u>\*, while NADH and FADH itself gets <u>re-oxidised</u>;
- As electrons pass down the chain, the release of energy in a series of redox reactions is coupled to the <u>phosphorylation of ADP to form **ATP**</u>\*;
- 5. <u>Protons</u> liberated in the oxidation of NADH and FADH is used to <u>establish</u> the **proton gradient**\* necessary for ATP synthesis (the H<sup>+</sup> can be either

pumped into intermembrane space or combines with oxygen to form water in the matrix).

- Re-oxidation of NADH and FADH allows the <u>regeneration of NAD<sup>+</sup> and</u> <u>FAD<sup>+\*</sup></u>, allowing it to pick up more protons and electrons from Krebs cycle, link reaction and glycolysis, so that these reactions can continue;
- 7. Each reduced NAD in the matrix yields <u>3 ATP;</u>
- and each reduced FAD in the matrix yields <u>2 ATP</u> through <u>oxidative</u> <u>phosphorylation</u>\*;
- During anaerobic respiration, re-oxidation of NADH allows the <u>regeneration</u> of <u>NAD</u><sup>+\*</sup> (during alcohol or lactate fermentation) allowing <u>glycolysis to</u> <u>continue</u>. [6 max]

# (b) Outline the main stages of the Krebs cycle.

- 1. Krebs cycle takes place in <u>matrix of mitochondria</u> and when oxygen is present;
- 2. <u>Acetyl CoA (2C)</u> formed through link reaction <u>combines with oxaloacetate</u> (4C) to form citrate (6C);
- 3. Citrate is <u>decarboxylated</u> and <u>dehydrogenated</u> to form <u> $\alpha$ -ketoglutarate</u> (5C) and <u>NADH</u>.
- 4. Each decarboxylation step results in a loss of carbon in the form of <u>a carbon</u> <u>dioxide;</u>
- Regeneration of oxaloacetate (4C) involves one decarboxylation step and three <u>dehydrogenation</u> steps to yield <u>2 NADH</u>\*, <u>1 FADH</u><sub>2</sub>\* and <u>1 CO</u><sub>2</sub>;
- Electrons (and protons) originally from glucose molecule have now been transferred to <u>electron carriers</u> <u>NAD</u><sup>+</sup>\* and <u>FAD</u>\*;
- 7. NAD<sup>+</sup> + 2H<sup>+</sup> + 2e<sup>-</sup>  $\rightarrow$  NADH + H<sup>+</sup> (or reduced NAD)
- 8. FAD + 2H<sup>+</sup> + 2e<sup>-</sup>  $\rightarrow$  FADH<sub>2</sub> (or reduced FAD)
- 1 <u>ATP</u>\* is also produced through <u>substrate-level phosphorylation</u> during this regeneration process;
- 10. All the carbon in glucose is lost as carbon dioxide;
- 11. Altogether <u>1 molecule of glucose will yield 6 NADH, 2 FADH<sub>2</sub> & 2 ATP</u> through the Krebs cycle. The coenzymes with their reducing power will next be transported to the electron transport chain where the bulk of ATP is generated. [8 max]

# (c) Explain how ATP is produced in anaerobic respiration.

- Anaerobic respiration takes place in the <u>absence of oxygen;</u>
   Oxygen serves as the *final electron acceptor*\* in *electron transport*
- <u>Oxygen</u> serves as the <u>final electron acceptor</u>\* in <u>electron transport</u>
   <u>chain</u>\*;
- 3. Without oxygen both *link reaction*\* and *Krebs cycle*\* subsequently stop;
- 4. As <u>NAD</u><sup>+</sup>\* cannot be regenerated \* from NADH\* in mitochondrion;
- 5. Anaerobic respiration takes place in the cytoplasm of the cell via *glycolysis*\*;
- 6. with a <u>net of 2 ATP molecules</u>\* produced via <u>substrate-level</u> <u>phosphorylation</u> for each glucose molecule oxidised;
- 7. <u>Pyruvate</u> is reduced by pyruvate dehydrogenase to <u>ethanol and carbon</u> <u>dioxide</u> with the <u>regeneration of NAD+ in yeast;</u>
- 8. <u>In mammal NAD<sup>+</sup></u> can be <u>regenerated</u> by converting <u>pyruvate</u> by lactate dehydrogenase <u>to lactate;</u>
- <u>NAD<sup>+</sup> regenerated</u> in <u>both processes</u> ensures steady supply of NAD is used for glycolysis to continue. [6 max]
