Queenstown Secondary School

Preliminary Examination 2024 Secondary Four Express Chemistry 6092/02

20 August 2024 Tuesday Time: 1115 – 1300h Duration: 1 hour 45 minutes

Setter:

Additional Materials:

Candidates answer on the Question Paper. No Additional Materials are required.

READ THESE INSTRUCTIONS FIRST

Write your name, class and index number on all the work you hand in. Write in dark blue or black pen. You may use an HB pencil for any diagrams or graphs. Do not use staples, paper clips, glue or correction fluid.

Section A

Answer **all** questions. Write your answers in the spaces provided.

Section B

Answer **one** question. Write your answers in the spaces provided.

The number of marks is given in brackets [] at the end of each question. A copy of the Periodic Table is printed on page 24.

The use of an approved scientific calculator is expected, where appropriate.

Examiner's Use				
Section A	/70			
Section B	/10			
B9				
B10				
TOTAL	/80			

Section A

Answer **all** questions.

A1 Use the list of substances to answer the questions.

calcium hydroxide	carbon monoxide	copper
hydrogen	magnesium	nitrogen
nitrogen dioxide	sulfur dioxide	zinc oxide

Each substance can be used once, more than once or not at all.

Name the substance(s) which

(a)	is added to soil to increase the pH,		
	calcium hydroxide		[1]
(b)	helps prevent iron in underwater pipes from rusting,		
	magnesium		[1]
(c)	lead to the formation of acid rain that corrodes limestone buildings,		
	sulfur dioxide and nitrogen dioxide		[1]
(d)	react in a 1:3 ratio in the Haber Process to produce ammonia.		
	nitrogen and hydrogen		[1]
		[Total: 4]	

- A2 Esters are commercially used as solvents for cosmetics, perfumes and glue.
 - (a) Propyl ethanoate has a characteristic odour of pears and is commonly used in fragrances. A bottle of perfume containing propyl ethanoate is left opened in a laboratory and it diffused throughout the laboratory.
 - (i) Give the names and draw the full structural formulae of the carboxylic acid and the alcohol that react to form propyl ethanoate.

$$\begin{array}{c|c} H & O \\ | & || \\ H - C - C - O - H \\ | \\ H \end{array} \qquad \begin{array}{c} H & H & H \\ | & | \\ H - C - C - C - O - H \\ | & | \\ H \end{array} \qquad \begin{array}{c} H & H - C - C - C - O - H \\ | & | \\ H & H \end{array}$$

$$\begin{array}{c} ethanoic acid \end{array} \qquad \begin{array}{c} propanol \end{array} \qquad [2]$$

(ii) The temperature of the laboratory is increased.

Explain, in terms of collisions between reacting particles, what effect would this have on the rate of diffusion of propyl ethanoate.

At higher temperatures, the reacting particles <u>move faster</u> leading [1] to a <u>higher frequency of effective collisions</u> between the particles,

resulting in a <u>higher rate of diffusion</u>.

[1]

(b) The table shows some information about different esters.

name	formula	relative molecular mass			
methyl methanoate	HCO ₂ CH ₃	60			
ethyl methanoate	$HCO_2C_2H_5$	74			
propyl methanoate	HCO ₂ C ₃ H ₇	88			
butyl methanoate	$HCO_2C_4H_9$	102			
pentyl methanoate	$HCO_2C_5H_{11}$	116			

Table 2

 Use information in the table to give one piece of evidence that suggests that the esters belong to the same homologous series.

The esters have the <u>same general formula</u>, $HCO_2C_nH_{2n+1}$. / [1] The esters have the <u>same functional group</u>, HCO_2 .

(ii) Which ester has the greatest rate of diffusion at room temperature and pressure? Explain your answer.

Methyl methanoate	[1]
It has the <u>lowest relative molecular mass</u> of <u>60</u> .	[1]

[Total: 7]

[1]

[1]

- A3 Seawater constitutes a rich source of various commercially important elements.
 - (a) Magnesium bromide is an important salt found in seawater.

Table 3 shows some information about two isotopes of bromine.

symbol	number of protons	number of neutrons	number of electrons
⁷⁹ 35Br	35	<u>44</u>	35
⁸¹ ₃₅ Br ⁻	<u>35</u>	46	<u>36</u>

Table 3

(i) Complete the table.

Use data from the table to explain the term *isotopes*.

Isotopes have the <u>same number of protons</u> (i.e. 35), but <u>different</u> [1] <u>number of neutrons</u> (i.e. 44, 46).

(iii) Chlorine is treated with a sample of seawater containing magnesium

bromide.

(ii)

Write the ionic equation for the reaction that occurs.

$$Cl_2(g) + 2Br^{-}(aq) \rightarrow 2Cl^{-}(aq) + Br_2(l)$$

- (iv) Explain why astatine does not react with aqueous magnesium bromide.
 Astatine, being less reactive than bromine, is unable to displace [1]
 bromine from its salt.
- (b) The distinctive smell of the seaside was thought to be due to ozone (O_3) .

Ozone reacts with aqueous potassium iodide as shown in the equation below.

$$2I^{-}(aq) + O_{3}(g) + 2H^{+}(aq) \rightarrow I_{2}(aq) + O_{2}(g) + H_{2}O(l)$$

(i) Describe what is observed when ozone is bubbled into aqueous potassium iodide.

```
The <u>colourless</u> solution turns <u>dark-brown</u>. [1]
```

(ii) Explain, in terms of oxidation states, why this is a redox reaction.

The iodine in potassium iodide undergoes <u>oxidation</u>, as the [1] oxidation state of <u>iodine</u> increases from -1 in l⁻ to <u>0 in l₂</u>.

The oxygen in ozone undergoes <u>reduction</u>, as the oxidation state [1] of oxygen decreases from 0 in O_3 to -2 in H_2O .

- (c) It is now known that the smell of the seaside is due to the presence of dimethyl sulfide, (CH₃)₂S.
 - (i) Draw a 'dot-and-cross' diagram for dimethyl sulfide, $(CH_3)_2S$.

```
covalent H H
| |
H - C - S - C - H
| |
H H
```

 (ii) Explain, in terms of bonding and structure, why dimethyl sulfide is a gas at room temperature and pressure.

Dimethyl sulfuide is a simple covalent molecule.

[1]

[2]

A small amount of heat energy is required to overcome the weak

intermolecular forces of attraction between molecules.

[Total: 10]

A4 (a) Complete the table.

alactrolyta	stato	alactrada	half equation at anode	effect on	
electiolyte	Slate	electiode	Hall-equation at anoue	electrolyte	
silver nitrate	aqueous	<u>silver</u>	<u>Ag (s) → Ag⁺ (aq) + e⁻</u>	<mark>no change</mark>	[1]
copper(II)	maltan	ana a bita	$2C^{+}(l) \ge C^{+}(c) + 2c^{-}$	fully	
chloride	molten	graphite	$20i (i) \neq 0i_2(g) + 2e$	decomposed	[1

Table 4.1

(b) The diagram below shows the electrolysis of concentrated aqueous sodium chloride. H⁺, OH⁻, Na⁺, CI

Fig. 4.2

(i) Write the half equation for the reaction that occurs at the negative electrode.

$\underline{2H^+ (aq) + 2e^- \rightarrow H_2 (g)}$

[1]

(ii) The volumes of products 1 and 2 should theoretically be the same.

Explain why the volume of product 1 is lesser.

As chlorine is <u>slightly soluble</u> in water, the volume collected is [1] lesser.

(iii) What happens to the resulting solution during the electrolysis?Explain your reasoning.

The resulting solution becomes increasingly alkaline.[1]With the removal of H⁺ and Cl⁻ ions, the remaining Na⁺ and OH⁻combine to form the strong alkali, NaOH.

(iv) The same apparatus can be used to electrolyse dilute aqueous sodium chloride. Give one similarity and one difference between the products of the electrolysis of concentrated and dilute aqueous sodium chloride. similarity At the cathode, H⁺ ions are discharged to form hydrogen [1] gas. difference At the anode, OH⁻ ions are discharged to form oxygen [1]

gas for dilute aqueous sodium chloride, while Cl⁻ ions are discharged to form <u>chlorine gas</u> for concentrated aqueous sodium chloride.

[Total: 7]

- A5 Ethanol is the intoxicating ingredient of many alcoholic beverages such as beer.
 - (a) Ethanol is manufactured by the reaction between ethene and steam.

Table 5

bond	C-C	C=C	C-H	O-H	C-0	C=O	0-0	0=0
bond energy in kJ/mol	346	610	414	463	358	804	144	498

(i) Using the bond energies provided in Table 5.1, calculate the enthalpy change for this reaction.

energy absorbed for bond-breaking = 610 + 4(414) + 2(463)

energy released for bond-forming = 346 + 5(414) + 358 + 463

enthalpy change of reaction = 3192 + (-3237) = <u>-45 kJ/mol</u>

enthalpy change -45 kJ/mol

(ii) The reaction between ethene and steam is exothermic.

Using ideas about bond breaking and bond forming, explain why the reaction is exothermic.

<u>More</u> energy is <u>released</u> in bond forming (i.e. C-C, C-H, C-O and O- [2] H) than <u>absorbed</u> in bond breaking (i.e. C=C, C-H and O-H).

[1]

Your diagram should show:

- the products of the reaction [exothermic]
- the activation energy for the reaction
- the enthalpy change of reaction, ΔH

energy $C_2H_4 + H_2O$

progress of reaction

[1]

- (b) Ethanol is also manufactured by the fermentation of glucose.
 - (i) Write a balanced chemical equation for this fermentation.

$$\underline{\mathsf{C}_6\mathsf{H}_{12}\mathsf{O}_6} \rightarrow \underline{\mathsf{2C}_2\mathsf{H}_5\mathsf{OH}} + \underline{\mathsf{2CO}_2}$$

(ii) Briefly describe this process.

Include in your answer the conditions needed for fermentation and how the ethanol is purified.

The fermentation of glucose can be carried out using yeast as[2]

catalyst. The mixture is kept at a temperature of about <u>37°C</u>,

producing a dilute solution of ethanol, with concentration <u>12-14%</u>.

The process is carried out under <u>anaerobic</u> conditions.

Ethanol is purified using fractional distillation. [1]

Queenstown Secondary School

- (c) Ethanol is oxidised by oxygen in the air to form ethanoic acid.
 Ethanol and ethanoic acid can be distinguised by chemical tests.
 Describe two of these chemical tests and the observations that allow you to make the distinctions.
 test 1 To 5 cm³ of sample, add 1 g of solid sodium carbonate. [1]
 observation With ethanol, there is no visible reaction.
 With ethanoic acid, effervescence is observed.
 test 2 To 5 cm³ of sample, add an equal volume of acidified potasisum [1]
 manganate(VII).
 observation With ethanol, the purple solution turns colourless.
 With ethanoic acid, no visible reaction.
 - [Total: 14]

[1]

A6 Poly(propene) and nylon are both used to make strong, waterproof ropes.Poly(propene) is an addition polymer. Nylon is a condensation polymer.

 (a) Describe one difference between addition polymers and condensation polymers.

Choose any one:

- The addition polymer contains the <u>C-C chain</u>, while the condensation polymer contains the <u>amide</u> or <u>ester linkages</u>.
- The formation of addition polymers <u>does not involve any loss of small</u> <u>molecules</u> (i.e. 1 product formed). While the formation of condensation polymers involves the <u>loss of small molecules</u> like water (i.e. 2 products formed).

- The formation of addition polymers involves the <u>C=C</u> functional group, while the formation of condensation polymers involves monomers with functional groups like <u>-NH₂</u>, <u>-COOH</u> and <u>-OH</u>.
- (b) Draw the structure of poly(propene), showing two repeat units.

(c) There are several different types of nylon. One type of nylon is nylon-6,6.

This is the repeating unit of nylon-6,6.

-														
	F	H H	н	н	н	н		0	н	н	н	н	0

(i) Draw the structures of the two monomers that react to form nylon-6,6.

$$\begin{array}{c|c} O & O \\ \| & \| \\ H - N - C_6 H_{12} - N - H \\ | & | \\ H & | \\ H & H \end{array} \end{array} + H$$

(ii) During the manufacturing process, the chain length of the nylon is controlled so that the nylon polymer molecules have an average relative molecular mass in the range 12 000 to 20 000.
 What is the range of the average number of repeating units in the nylon-6,6 molecules? Show your working.

$$M_r \text{ of } C_{12}H_{22}N_2O_2 = 226$$
[1]

range <u>54 to 88</u> [1]

[2]

[Total: 6]

A7 Read the information about elements and compounds in the Earth.

The Earth's crust is the thin outer layer of the Earth. The pie charts show a comparison of the percentages of elements in the whole Earth and in the Earth's crust.

In the Earth's crust, silicon and oxygen are the most abundant elements. Rocks such as quartz are made of covalently bonded compounds of silicon and oxygen. Typically, quartz contains 46.7% silicon and 53.3% oxygen by mass.

Some rocks such as feldspars contain ionic silicate compounds. These contain metal ions ionically bonded to silicate ions.

Examples of naturally occurring silicates are shown in the table below.

name of silicate compound	formula
forsterite	Mg ₂ SiO ₄
phenacite	Be ₂ SiO ₄
anorthite	CaAl ₂ Si ₂ O ₈
microcline	KA/Si ₃ O ₈

Table 7.2

The formulae of the silicate compounds are not simple. Some silicate compounds contain one type of metal ion, others contain more than one. All silicate ions contain silicon and oxygen, but the numbers of the atoms and the charges on the ions vary. For example,

- phenacite (Be₂SiO₄) contains only Be²⁺ metal ions and the formula of its silicate ion is SiO₄⁴⁻,
- microcline (KA/Si₃O₈) contains K⁺ and Al³⁺ metal ions and the formula of its silicate ion is Si₃O₈⁴⁻.

(a) Scientists believe that the centre of the Earth is made from an inner core made mainly of iron.

What evidence from the pie charts supports this idea?

The pie charts show that there is <u>35%</u> of iron in the whole Earth, while [1] there is only <u>6%</u> in the Earth's crust. This implies that <u>29%</u> of the iron is in the inner core of the Earth.

(b) (i) Use the information to work out the empirical formula and hence the name of the main compound in quartz.

	Si	0
percentage	46.7	53.3
Ar	28	16
no. of moles	1.6679	3.3333
÷ 1.6679	1	2

empirical formula <u>SiO</u>₂ [1]

name silicon dioxide [1]

(ii) There are other compounds of oxygen found in the Earth's crust as well as quartz. One such example is potassium oxide.

The table shows some differences between the properties of potassium oxide and the compound in **(b)(i)**.

Table 7.3

compound	molting point / °C	electrical conductivity
compound	mening point / °C	under room conditions
potassium oxide	740	does not conduct
compound in (b)(i)	2230	does not conduct

Explain, in terms of bonding and structure, why potassium oxide [ionic]	
and the compound in (b)(i) [giant covalent] have different properties.	
Potassium oxide is an i <u>onic</u> compound.	[1]
A <u>large</u> amount of heat energy is required to overcome the <u>strong</u>	
electrostatic forces of attraction between oppositely-charged ions.	
Silicon dioxide is a giant covalent molecule.	[1]
An even larger amount of heat energy is required to overcome the	
stronger covalent bonds between atoms.	
For potassium oxide, the ions are held rigidly in fixed positions in	[1]
the solid state. The <u>absence of mobile charged</u> ions prevents the	
electric current from being carried.	
For silicon dioxide, all valence electrons are used for bonding. The	[1]
absence of mobile charged electrons prevents the electric current	
from being carried.	

(c) Give the formulae and charges of the ions present in anorthite.

<u>Ca²⁺</u>, <u>Al³⁺</u> and <u>Si₂O₈⁸⁻</u>

[1]

(d) Beryllium and silicon can both be extracted from the mineral phenacite.
 Show by calculation that 1 kg of phenacite contains a larger mass of silicon than beryllium but a larger number of moles of beryllium atoms than silicon atoms.

*M*_r of phenacite = 110

mass of silicon in phenacite =
$$\frac{28}{110}$$
 x 1000 g = 255 g (to 3 s.f.) [1]

mass of beryllium in phenacite = $\frac{2(9)}{110}$ x 1000 g = <u>164 g</u> (to 3 s.f.) [1]

From the above calculations, 1 kg of phenacite contains a larger mass of silicon than beryllium.

no. of mol. of silicon =
$$\frac{254.545g}{28}$$
 = 9.09 mol (to 3 s.f.) [1]

no. of mol. of beryllium =
$$\frac{163.636g}{9}$$
 = 18.2 mol (to 3 s.f.) [1]

From the above calculations, 1 kg of phenacite contains a larger number of moles of beryllium atoms than silicon atoms.

[Total: 12]

A8 A series of experiments was carried out to investigate the effect of different catalysts on the rate of a reaction.

The table shows the time taken for the reaction to finish when different metal compounds were used as catalysts.

The metal compounds contained Group 1 metals, Group 2 metals or transition metals.

ovporimont	catalvet	temperature at start	time taken for reaction to finish
experiment	Catalyst	/ °C	/ s
1	NaCl	19	45
2	FeCl ₂	20	22
3	CoCl ₂	19	26
4	MgCl ₂	20	46
5	NaNO ₃	19	45
6	Fe(NO ₃) ₂	20	22
7	Fe(NO ₃) ₃	19	15
8	Co(NO ₃) ₂	19	26
9	Mg(NO ₃) ₂	19	46

Table 8

(a) Explain, in terms of collisions and energy, the effect of a catalyst on the rate of a reaction.

A catalyst provides an <u>alternative pathway</u> with a <u>lower activation energy</u> [1] for the reaction to proceed, leading to a <u>higher frequency of effective</u> [1]

<u>collisions</u> between the particles, resulting in a <u>higher rate</u> of reaction.

(b) Group 1 and Group 2 metal compounds are less effective than transition metal compounds as catalysts.

Explain how the information in the table supports this statement.

Comparing experiments 5, 7, 8 and 9, with the same starting temperature [1] of 19°C, Group 1 and 2 metal compounds are less effective as the time taken for reaction to finish is longer (i.e. NaNO₃ takes <u>45s</u>, while Mg(NO₃)₂ takes <u>46 s</u>), as compared to the transition metal compounds [1] which take a shorter time (i.e. Fe(NO₃)₃ takes <u>15s</u>, and Co(NO₃)₂ takes 26s.

(c) Iron is a transition metal.

Two different iron ions were used in the experiments.

- (i) Give the formulae of the two ions. Fe²⁺ and Fe³⁺
 (ii) Which iron ion appears to be the more effective catalyst?
 Explain your reasoning.
 Iron(III) ion is the more effective catalyst.
 [1]
 Comparing experiments 6 and 7, iron(III) ion took a shorter time
 (i.e. 15s in experiment 7) to complete the reaction, as compared to
 that of iron(II) ion (i.e. 22s in experiment 6), despite the slight
 change in temperature.
 (iii) State one other property of transition metals.
 - They forms <u>coloured coompounds</u> when hydrated. [1]

(d) A student wrote this conclusion from the results in the table.

The type of anion in the catalyst compound does not affect the rate of reaction.

(i) Do you agree with this conclusion?

Use the results to explain your reasoning.

<u>Yes</u>.

[1]

Comparing experiments 1 and 5, both Na⁺ compounds took <u>45s</u> to [1]

complete the reaction, regardless of the anion.

Also, comparing experiments 2 and 6, both Fe²⁺ compounds took

<u>22s</u> to complete the reaction, regardless of the anion.

(ii) Predict the time taken for the reaction to finish if iron(III) chloride was used as a catalyst.

<u>15s</u>

[1]

[Total: 10]

Section B

Answer **one** question from this section.

B9 A factory is suspected of releasing non-biodegradable toxic waste such as calcium ions, aluminium ions, zinc ions and nitrate ions into the nearby river.

A scientist tested two samples of the river water by adding excess aqueous sodium hydroxide and aqueous ammonia respectively, followed by warming with aluminium foil. He recorded his observations in Table 9 below.

tost	on adding	on adding oxees	on warming with
lesi	a few drops	on adding excess	aluminium foil
aqueous sodium hydroxide	white precipitate formed	white precipitate, soluble in excess giving a colourless solution	no visible reaction
aqueous ammonia	white precipitate formed	white precipitate, some soluble in excess giving a colourless solution, some remained insoluble in excess	gas evolved turns damp litmus paper blue

Table 9

Based on this information, the scientist claimed that the factory had indeed been releasing aluminium ions, zinc ions and nitrate ions into the river. However, the factory owner argued that this data showed that the factory was only releasing aluminium ions and zinc ions, but not nitrate ions.

(a) (i) Explain how the data shows that calcium ions are absent, but both aluminium ions and zinc ions are present in the river water.
 From the test with aqueous NaOH, the white precipitate formed is [1] soluble in excess, implying that both Al³⁺ ions and Zn²⁺ ions are present. If Ca²⁺ ion is present, then some white precipitate formed [1] is <u>insoluble</u> in excess.

From the test with aqueous NH₄OH, some white precipitate formed [1] is <u>soluble</u> in excess, confirming that Zn^{2+} ions are present, while some white precipitate formed is <u>insoluble</u> in excess, confirming that Al^{3+} ions are present.

(ii) The scientist claims that nitrate ions are detected in the river water as the test with aqueous ammonia produced ammonia gas.

Do you agree? Explain your answer.

<u>No</u>, the ammonia gas produced could be due to the presence of [1] aqueous ammonia.

To test for nitrate ions, the scientist should use <u>warm aqueous</u> [1] sodium hydroxide and aluminium foil.

(b) The river water also contained trace amounts of chloride ions.

Describe how you would carry out a test to show the presence of chloride ions in a solution. Include the observations you would expect.

test: To a 2 cm³ sample of river water, add an equal volume of dilute[1]acid, followed by aqueous silver nitrate.[1]result: white precipitate formed[1]

Describe how a pure sample of zinc chloride crystals can be prepared from insoluble zinc carbonate.

- 1. Add excess zinc carbonate [base] powder to warm dilute
 [1]

 <u>hydrochloric acid</u> [acid].
- 2. <u>Filter</u> the mixture to remove the excess zinc chloride.
- 3. <u>Heat</u> the filtrate till it is saturated. [1]
- Allow the solution to <u>cool</u> and crystals of zinc chloride will form.
 <u>Filter</u> off the crystals.
- 5. <u>Wash</u> the crystals with distilled water. [1]
- 6. <u>Dry</u> the pieces of crystals between two pieces of filter paper.

[Total: 10]

- **B10** The reactivity series summarises information about the reactions of metals with acids and water, displacement reactions and the extraction of metals from their ores.
 - (a) A student carried out some experiments to place four metals, W, X, Y and Z in order of reactivity. The table shows the results.

	metal W	metal X	metal Y	metal Z
solution of W nitrate		×	×	×
solution of X nitrate	✓		\checkmark	\checkmark
solution of Y nitrate	✓	×		\checkmark
solution of Z nitrate	✓	×	×	

Table 10.1

[key: \checkmark = shows a reaction happened; \star = shows no reaction happened]

(i) Place the metals in order of reactivity, starting with the most reactive.

W > Z > Y > X

(ii) Metal Z reacts with hydrochloric acid.

What would you see when metal Z reacts with hydrochloric acid?

Explain your reasoning.

Effervescence is observed.

[1]

[1]

Metal Z, being a <u>reactive</u> metal (i.e. above H in the reactivity [1]

series), reacts with acid to displace hydrogen gas.

(iii) The student carried out further experiments to place metal **M** in the list.

She used dilute hydrochloric acid and samples of the metals.

She found out that metal **M** is the fourth most reactive metal.

Describe the experiments that the student carried out.

Your answer should include

- the experiments that she carried out using dilute hydrochloric acid and samples of the metals,
- the measurements that she made,
- how the results showed that metal M is the fourth most reactive metal.

Approach:

The student measured and compared the <u>volume of hydrogen gas</u> collected for a <u>metal</u> of fixed mass (i.e. 0.5 g each of metals W, X, Y, Z and M) to react completely with <u>dilute hydrochloric acid</u> of a fixed concentration (i.e. 1 mol/dm³)-and volume (30 cm³) over a 2-

minute duration.

Procedure:

- 1. Using a 50 cm³ measuring cylinder, measure 30 cm³ of HC*l* and place it in a 250 cm³ conical flask.
- 2. Transfer the dilute hydrochloric acid into the conical flask, connect a gas syringe
- Using an electronic mass balance, measure 0.5 g of metal W and add it to the conical flask.
 Stopper the conical flask and connect a gas syringe to the conical flask using a delivery tube. Start the stopwatch immediately.
- 4. Stop the stopwatch when it reaches 2 minutes. Record the volume of gas produced in a table of suitable format.

Conclusion:

[1]

Metal W will have the highest volume of hydrogen gas collected, followed by metals Z, Y, <u>M</u> (i.e. 4^{th} most reactive) and X.

[1]

[1]

(b) The student also carried out some experiments to investigate the reduction of three metal oxides by hydrogen.

The table shows the appearance of each metal oxide when cold.

Table 10.2

experiment	metal oxide	colour when cold
1	calcium oxide	white
2	copper oxide	red
3	lead oxide	yellow

(i) What would you expect to see happen in each experiment?

Explain your answer.

There is no visible reaction for experiments 1 and 3.[1]

Calcium and lead, being more reactive than hydrogen, cannot be

displaced from their oxide by hydrogen.

In experiment 2, the <u>red</u> copper oxide turns <u>red-brown</u>. [1]

Copper, being less reactive than hydrogen, can be displaced from

its oxide by hydrogen.

(ii) In which tube would you expect to see the fastest reaction?

Explain your answer.

The tube containing <u>copper oxide</u> .	[1]
Copper, being the <u>least reactive metal</u> , forms the <u>least stable metal</u>	[1]

oxide, hence the oxide is more readily reduced by hydrogen.

		<u>Dry</u> t	ne pieces of crystals between two pieces of filter paper.	
B10	(a)	(i)	W > Z > Y > X	[1]
		(ii)	Effervescence is observed.	[1]
			Metal Z , being a <u>reactive</u> metal (i.e. above H in the reactivity	[1]
			series), reacts with acid to displace hydrogen gas.	
		(iii)	Approach:	[1]
			The student measured and compared the volume of hydrogen gas	
			collected for a <u>metal</u> of fixed mass (i.e. 0.5 g each of metals W , X ,	
			Y , \angle and W) to react completely with <u>dilute hydrochloric acid</u> of a fixed constration (i.e. 4 mal/dm ³) and uphyme (20 mm ³) areas 2	
			Tixed concentration (I.e. 1 mol/dm [°])-and volume (30 cm [°]) over a 2-	

		 <u>Procedure</u>: 5. Using a 50 cm³ measuring cylinder, measure 30 cm³ of HC<i>l</i> and place it in a 250 cm³ conical flask. 6. Transfer the dilute hydrochloric acid into the conical flask, connect a gas syringe 7. Using an electronic mass balance, measure 0.5 g of metal W and add it to the conical flask. Stopper the conical flask and connect a gas syringe to the conical flask using a delivery tube. Start the stopwatch immediately. 8. Stop the stopwatch when it reaches 2 minutes. Record the volume of gas produced in a table of suitable format. 	[1]
		<u>Conclusion</u> : Metal W will have the highest volume of hydrogen gas collected, followed by metals Z , Y , <u>M</u> (i.e. 4 th most reactive) and X .	[1]
(b)	(i)	There is <u>no visible reaction</u> for experiments 1 and 3. Calcium and lead, being <u>more reactive</u> than hydrogen, <u>cannot be</u> <u>displaced</u> from their oxide by hydrogen.	[1]
		In experiment 2, the <u>red</u> copper oxide turns <u>red-brown</u> . Copper, being <u>less reactive</u> than hydrogen, <u>can be displaced</u> from its oxide by hydrogen.	[1]
	(ii)	The tube containing <u>copper oxide</u> . Copper, being the <u>least reactive metal</u> , forms the <u>least stable metal</u> <u>oxide</u> , hence the oxide is <u>more readily reduced</u> by hydrogen.	[1]
